

Using Fish Community-Based Measures of Stream Health to Develop Nutrient Criteria for Virginia Streams and Rivers

Greg Garman

William Shuart

Jennifer Ciminelli

VCU Center for Environmental Studies
(Academic Advisory Committee of DEQ)

Statement of the Problem

Develop statistically-valid, objective nutrient criteria based on definitions of stream health that incorporate living resources and related uses

Proof-of-Concept *re:* nutrient criteria in non-wadeable streams, based on fish community metrics (e.g. IBI)

Objectives

- Assemble a single, geo-referenced database combining stream nutrient concentrations, nutrient loadings, and fish community metrics
- Evaluate patterns among the parameters and metrics; do statistically valid relationships exist?
- Recommendations *re:* developing numeric nutrient criteria from data, if patterns exist

Pilot Study Approach

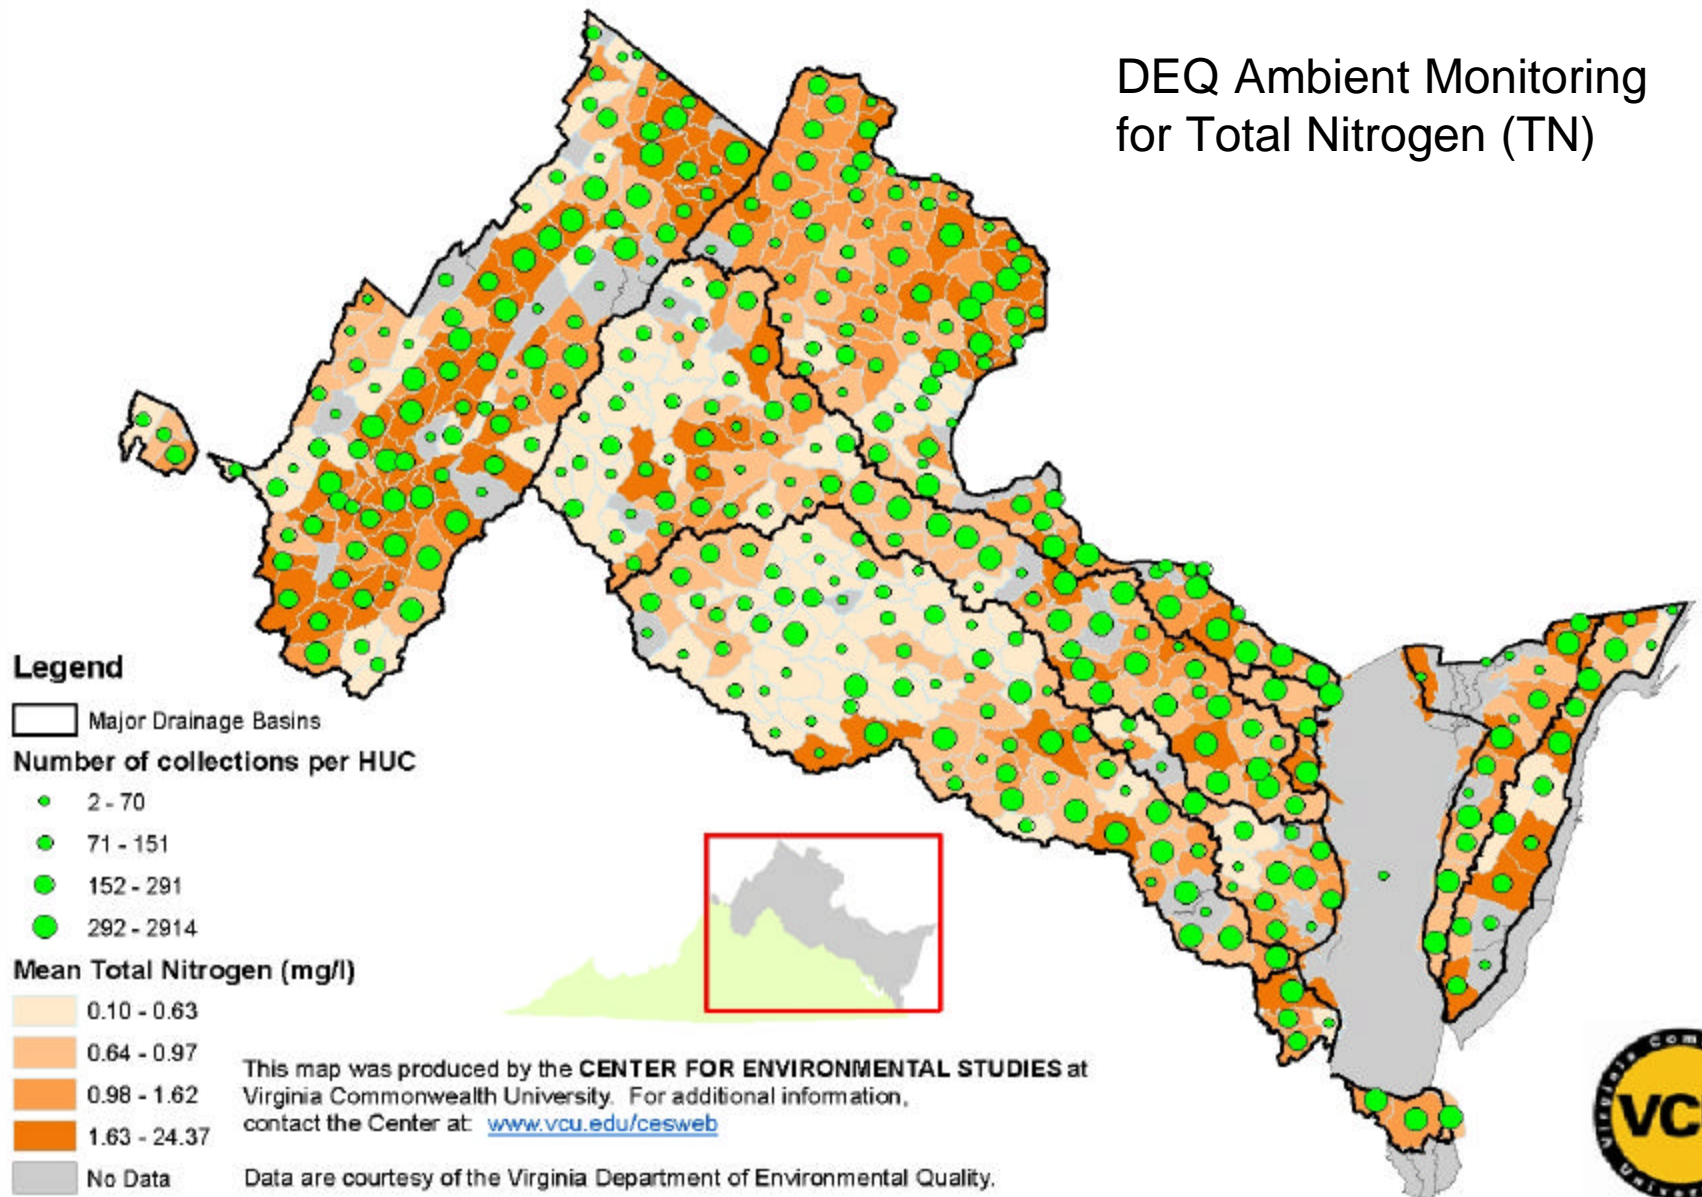

- Identify existing data sources
- Focus the analysis (parameters/regions)
- Integrate relevant data
- Combine data by geospatial units (HUCs)
 - a ‘one-to-many’ relationship for each 6th-order HUC
- Exploratory (graphical) analyses
 - multiple comparisons among parameters and regions
- Recommendations for ‘next steps’

Major Data Sources

1. DEQ Ambient Monitoring Program

- 600K records from Roger Stewart
- Nutrient concentrations (TN, TP only)
- Chlorophyll-*a* concentrations**
- Chesapeake Bay Watershed (*excluding* the James), Coastal Zone, Eastern Shore, Shenandoah basin
- Freshwater streams & rivers only

DEQ Ambient Monitoring for Total Nitrogen (TN)

DEQ Ambient Monitoring for Total Phosphorus (mg/l)

Legend

Number of samples in HUC

- 1 - 53
- 54 - 136
- 137 - 370
- 371 - 847

Major Drainage Basins

Watersheds

Average Total Phosphorus (mg/l)

- 0.010 - 0.045
- 0.046 - 0.068
- 0.069 - 0.130
- 0.131 - 12.382
- No Data

DEQ Ambient Monitoring for Chl-a

Legend

Watersheds

Number of collections per HUC

- 0.50 - 1.39
- 1.40 - 3.05
- 3.06 - 11.06
- 11.07 - 249.02

Major Drainage Basins

Watersheds

Mean Chlorophyll-a (ug/l)

- 0.50 - 1.39
- 1.40 - 3.05
- 3.06 - 11.06
- 11.07 - 249.02

No Data

Major Data Sources

1. DEQ Ambient Monitoring Program

600K records from Roger Stewart

Nutrient concentrations (TN, TP only)

Chlorophyll-a concentrations**

Chesapeake Bay Basin, exclusive of the James

2. DCR NPS Nutrient Loadings

Karl Huber, 2006 NPS Assessment

TN & TP; edge-of-stream model outputs

3. VCU's INSTAR program

fish community/ecological models; infer stream health

INSTAR at a glance

The Database

Aquatic resources and in-stream habitat information

>200K records representing >1,925 stream reaches (probabilistic design)

Ecological models (i.e., *virtual* reference streams) to support **objective** assessment and analysis of stream health

The Application

Interactive and internet based (ArcIMS; MS SQL)

High-resolution spatial data (GIS) coverages

Wide range of functions and database queries supported; new '*lite*' interface in beta testing

Accessible to anyone with a PC and modem

<http://instar.vcu.edu>

INSTAR Supports Two Bioassessment Protocols:

Modified Index of Biotic Integrity (mIBI)

Metrics:

1. Native species richness
2. Number of R, T, & E species
3. Number of non-indigenous species
4. Number of 'critical' species
5. Number of tolerant species
6. Number of intolerant species

Regional Scoring Criteria
Ranges between 6-30
Broad geospatial scales
(HUCs)

Virtual Stream Assessment (VSA)

Percent comparability to *virtual* regional reference conditions

Empirical range: 8-92% of region-appropriate VSA model

Statistics currently support several regional VSA models, including lower piedmont, coastal zone and Shenandoah basin

Intermediate spatial scales (reaches)

Quantitative data are inputs

Virtual Stream Model—Lower Coastal Plain

$$\text{Virtual Reference Stream (100\%)} = 0.05(EP) + 0.02(Rich) - 0.19(Chnlalt) - 0.1(Intol) + 0.18(Toler) - 0.05(HBI) + 5.67$$

EP = Ephemeroptera & Plecoptera taxa

Rich = fish species richness (native)

Chnlalt = percent channel alteration

Intol = percent intolerant species

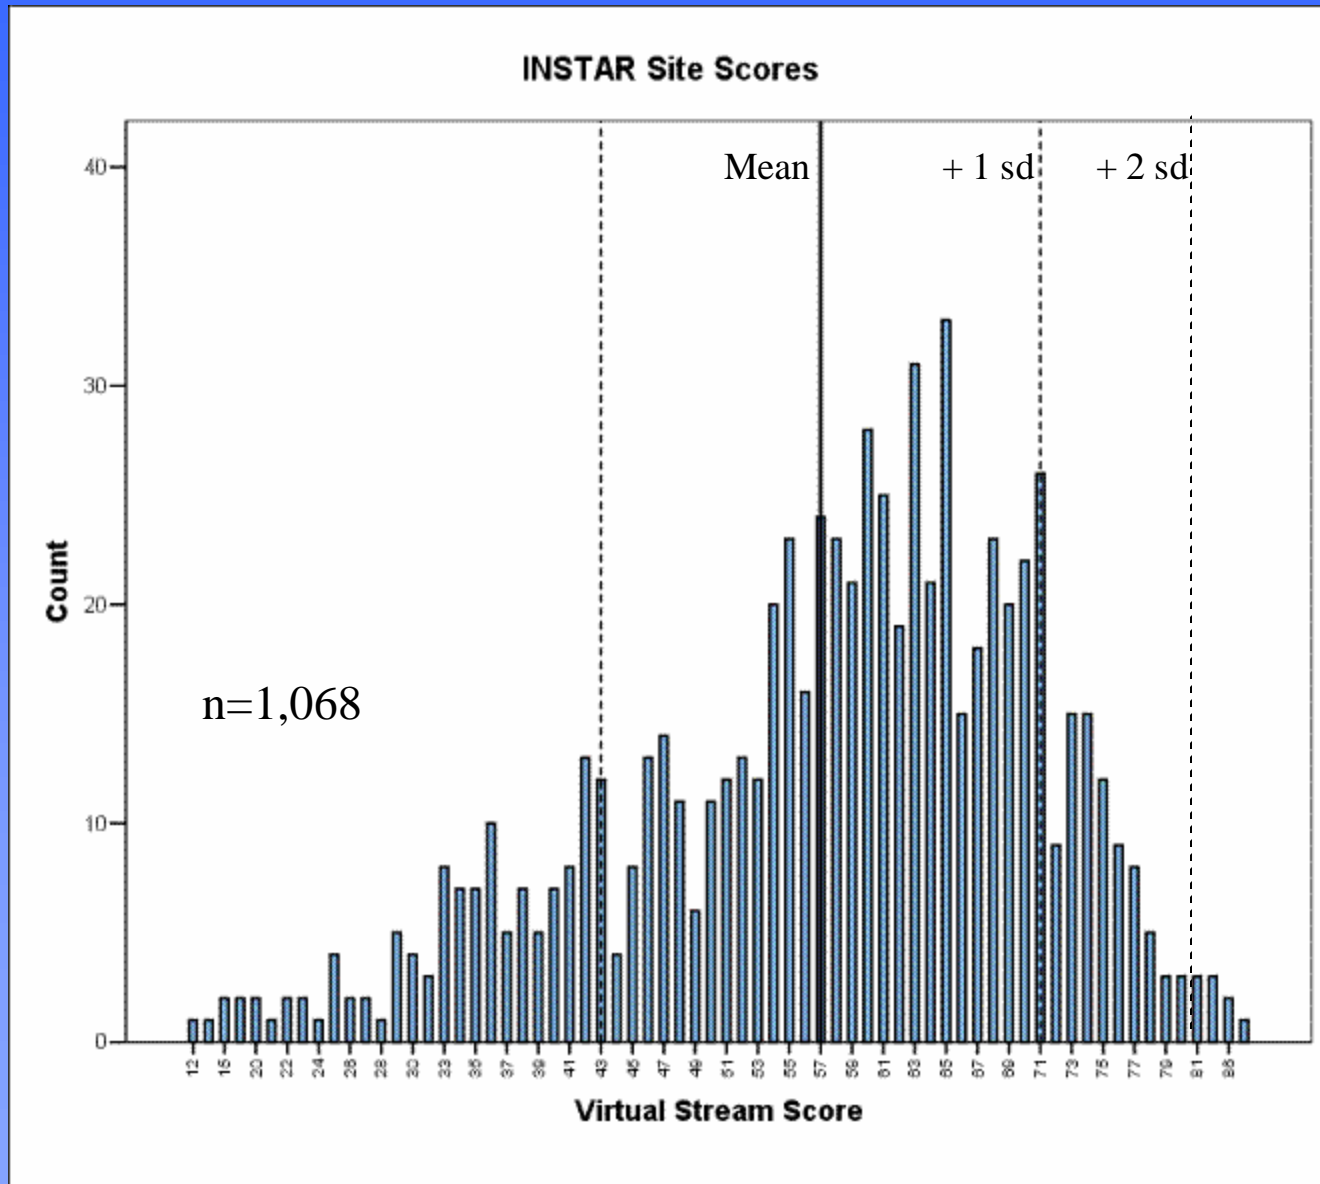

Toler = number tolerant species

HBI = Hilsenhoff Biotic Index

adjusted R square = 0.72

Findings

- Significant negative relationship among stream health (fish metrics) vs. [nutrients] or loadings; Chl-*a* is different
- Pattern consistent among regions and basins; similar to limited literature
- Many limitations, however, with current data and analyses
- Demonstrates proof-of-concept for using fish community data to establish criteria?

Next Steps

- Focus on *non-wadeable* streams and rivers; expand geographic coverage
- Operational definition of 'non-wadeable'
- Leverage DEQ's ProbMon program to develop a synoptic dataset for the entire state ('06-'08)
- More rigorous statistical analyses; build more VSA fish community models for other regions
- What are the underlying mechanisms of fish community 'response' to [nutrients]?
- Criteria development; conditional probability approach
- Validation of draft criteria
